Abstract

Building high-performance virtual machines is a complex and expensive undertaking; many popular languages still have low-performance implementations. We describe a new approach to virtual machine (VM) construction that amortizes much of the effort in initial construction by allowing new languages to be implemented with modest additional effort. The approach relies on abstract syntax tree (AST) interpretation where a node can rewrite itself to a more specialized or more general node, together with an optimizing compiler that exploits the structure of the interpreter. The compiler uses speculative assumptions and deoptimization in order to produce efficient machine code. Our initial experience suggests that high performance is attainable while preserving a modular and layered architecture, and that new high-

These implementations can be characterized in the following way:

- Their performance on typical applications is within a small multiple (1-3x) of the best statically compiled code for most equivalent programs written in an unsafe language such as C.
- They are usually written in an unsafe, systems programming language (C or C++).
- Their implementation is highly complex.
- They implement a single language, or provide a bytecode interface that advantages a narrow set of languages to the detriment of other languages.

In contrast, there are numerous languages that are popu-

GraalVM is a new runtime system that provides instant startup and low footprint for Java applications via ahead-of-time compilation. It also has polyglot capabilities that allows to execute and interoperate with many languages including JavaScript, Python, Ruby, WebAssembly, and native languages. This session discusses lessons learned while turning the vague research ideas behind GraalVM into a released product over the timespan of more than a decade, how we experienced our entry to the developer community, and also major technical questions where we now think differently. ...więcej

Unleash the power of your applications with Micronaut and GraalVM

Session type: ARCHITECTURE

In this talk, Micronaut committer Álvaro Sánchez-Mariscal, will demonstrate how you can quickly build optimised Microservices with Micronaut & GraalVM Native Image. Attendees will learn how the combination of GraalVM Native Image and Micronaut can lead to efficient, highly performant, and optimised applications that can be perfectly deployed to environments like Kubernetes or serverless platforms. There will be a live coding demo of an application using Micronaut Data and GraalVM.

Álvaro Sánchez-Mariscal Arnaiz

Álvaro is a passionate developer and agile enthusiast with over 22 years of experience. He is now a Principal Member of Technical Staff at Oracle Labs, where he is a Micronaut committer, helping to maintain and evolve the open-source framework. Before that, he was a Staff Engineer at VMWare, where he led the creation of new products to build, package, verify and publish software solutions with confidence in the VMware Marketplace. Previously, he spent some years working in different industries like gambling games (Odobo) and fintech (4Finance). Prior to that, he created his own company, Salenda, in 2005, a software factory and Atlassian Solution Partner headquartered in Madrid, Spain. Adaptavist acquired Salenda in 2019. Previously, he worked at companies like IBM BCS, Sun Microsystems or BEA Systems, where he was recognised as BEA Technical Director, an MVP awards program. He was also one of the initial founders and member of the Board of Directors of javaHispano in 2002, the world's largest Spanish-speaking Java User Group. Álvaro has spoken in 20 different countries at conferences like Devoxx BE/FR/MA, several Voxxed Days, GeeCON, JavaLand, JavaZone, jPrime, Codemotion and Commit Conf, among others. In his spare time, as well as coding and experimenting with new technologies, he likes to spend time with his wife and children, support CD Leganés football team, and play paddle tennis.

Going AOT: Everything you need to know about GraalVM for Java

Session type: ARCHITECTURE

In the past few years GraalVM got widely adopted by the Java ecosystem, and now it's hard to imagine starting a new project, especially for the cloud, without at least considering going native. However, taking a new technology to production requires research and preparation. What is the best way to build and deploy such native executables? Once deployed, how can I monitor them? Can I test them as I do with regular Java applications? What if startup is less important, how do I optimize for peak performance and latency? How do I use frameworks and libraries? This session will cover all of those steps and illustrate them with examples. We'll also have plenty of time for questions – bring them all!

Alina Yurenko

Alina is a developer advocate for GraalVM at Oracle Labs, a research & development organization at Oracle. Loves both programming & natural languages, compilers, and open source.

Truffle Language Implementation Framework

The Truffle language implementation framework (Truffle) is an open source library for building tools and programming languages implementations as interpreters for self-modifying Abstract Syntax Trees. Together with the open source Graal compiler, Truffle represents a significant step forward in programming language implementation technology in the current era of dynamic languages.

GraalVM

C1 - Client Compiler

The Client Compiler, also known as C1, is a type of JIT compiler optimized for faster startup time. It strives to optimize and compile code as quickly as possible.

C1 - Client Compiler

C2 - Server Compiler

The Server Compiler, also known as C2, is a type of JIT compiler optimized for better overall performance.

C2 observes and analyzes the code for a longer period compared to C1. This allows C2 to make better optimizations in the compiled code.

C2 - Server Compiler

WE NEED TO GO
DEEPER
memegenerator.net

A JIT compiler can recompile parts of the code during the program's execution thanks to profiling.

This allows for optimizations based on real-time execution data, which static compilers are unable to consider.

Dynamic optimization

Tiered Compilation

Speculative optimization

Speculative optimization

```java
interface NumberAdder {
    void addRandomNumber(int base);
}

class SimpleAdder implements NumberAdder {
    public void addRandomNumber(int base) {
        double result = Math.random() + base;
    }
}

class LoggingAdder implements NumberAdder {
    public void addRandomNumber(int base) {
        double result = Math.random() + base;
        System.out.println("Computed value: " + result);
    }
}
```

```java
public class DeoptimizationExample {
    public static void main(String[] args) {
        NumberAdder adder = new SimpleAdder();

        for (int i = 0; i < 10000; i++) {
            if (i == 5000) {
                adder = new LoggingAdder();
            }
            adder.addRandomNumber(10);
        }
    }
}

interface NumberAdder {
    void addRandomNumber(int base);
}

Second, Graal evaluates the constant objects when it parses the bytecodes and presents those as concrete Java objects to the analysis. Hence, the Graal IR gives a more concrete and easier to use representation of the analyzed code than the bytecode. The bytecode preprocessing step reduces the code complexity and enables the points-to analysis to save some iterations.

GraalVM in Just-In-Time (JIT) Compilation Mode

Which Version of JDK Should I Use?

English 한국어

To build and run Java applications, a Java Compiler, Java Runtime Libraries, and a Virtual Machine are required that implement the Java Platform, Standard Edition ("Java SE") specification.

The OpenJDK is the open source reference implementation of the Java SE Specification, but it is only the source code. Binary distributions are provided by different vendors for a number of supported platforms. These distributions differ in licenses, commercial support, supported platforms, and update frequency.

This site gives independent, yet opinionated recommendations.

GraalVM in Just-In-Time (JIT) Compilation Mode

JEP 243: Java-Level JVM Compiler Interface

Owner	John Rose
Type	Feature
Scope	JDK
Status	Closed / Delivered
Release	9
Component	hotspot / compiler
Discussion	hotspot dash compiler dash dev at openjdk dot java dot net

Updated	2019/09/16 19:05
Issue	8062493

Summary

Develop a Java based JVM compiler interface (JVMCI) enabling a compiler written in Java to be used by the JVM as a dynamic compiler.

Goals

- Allow a Java component programmed against the JVMCI to be loaded at runtime and used by the JVM’s compile broker.
- Allow a Java component programmed against the JVMCI to be loaded at runtime and used by trusted Java code to install machine code in the JVM that can be called via a Java reference to the installed code.

JEP 295: Ahead-of-Time Compilation

Owner	Vladimir Kozlov
Type	Feature
Scope	Implementation
Status	Closed / Delivered
Release	9
Component	hotspot / compiler
Discussion	hotspot dash compiler dash dev at openjdk dot java dot net

Endorsed by	Vladimir Kozlov
Created	2017/10/20 20:03
Updated	2018/03/28 01:58
Issue	8189751

Summary

Enable the Java-based JIT compiler, Graal, to be used as an experimental JIT compiler on the Linux/x64 platform.

Non-Goals

It is not a goal to meet or beat the performance of the existing JIT compilers.

Motivation

Graal, a Java-based JIT compiler, is the basis of the experimental Ahead-of-Time (AOT) compiler introduced in JDK 9. Enabling it to be used as an experimental JIT compiler is one of the initiatives of Project Metropolis, and is the next step in investigating the feasibility of a Java-based JIT for the JDK.

Updated	2021/08/05 02:44
Issue	8263327

Summary

Remove the experimental Java-based ahead-of-time (AOT) and just-in-time (JIT) compiler. This compiler has seen little use since its introduction and the effort required to maintain it is significant. Retain the experimental Java-level JVM compiler interface (JVMCI) so that developers can continue to use externally-built versions of the compiler for JIT compilation.

Motivation

Ahead-of-time compilation (the `jaotc` tool) was incorporated into JDK 9 as an experimental feature via JEP 295. The `jaotc` tool uses the Graal compiler, which is itself written in Java, for AOT compilation.

The Graal compiler was made available as an experimental JIT compiler in JDK 10 via JEP 317.

We have seen little use of these experimental features since they were introduced, and the effort required to maintain and enhance them is significant. These features were not included in the JDK 16 builds published by Oracle, and no one complained.

GraalVM in Just-In-Time (JIT) Compilation Mode

Galahad

Galahad's primary goal is to contribute Java-related GraalVM technologies to the OpenJDK Community and prepare them for possible incubation in a JDK main-line release.

doug.simon@oracle.com christian.wimmer@oracle.com

Abstract

An abstract syntax tree (AST) interpreter is a simple and natural way to implement a programming language. However, it is also considered the slowest approach because of the high overhead of virtual method dispatch. Language implementers therefore define bytecodes to speed up interpretation, at the cost of introducing inflexible and hard to maintain bytecode formats. We present a novel approach to implementing AST interpreters in which the AST is modified during interpretation to incorporate type feedback. This tree rewriting is a general and powerful mechanism to optimize many constructs common in dynamic programming languages. Our system is implemented in Java™ and uses the static typing and primitive data types of Java elegantly to avoid the cost of boxed representations of primitive values in dynamic programming languages.

Categories and Subject Descriptors D.3.4 [*Programming Languages*]: Processors—Run-time environments, Optimization

General Terms Algorithms, Languages, Performance

Keywords Java, JavaScript, dynamic languages, virtual machine, language implementation, optimization

studied [9, 22]. Bytecodes are a virtual instruction set, i.e, they can be defined freely by language implementers without worrying about hardware constraints. There are two different strategies when defining bytecodes. We believe that both are cumbersome when implementing a new language:

- Language-independent bytecodes aim to provide an instruction set that is suitable for many languages. Java™ bytecodes [17], originally designed primarily for the Java programming language, are now used for many languages. The Common Intermediate Language (CIL) [8], which is used by the .NET system, was specifically designed for multiple languages. Language-independent bytecodes provide only general instructions whose semantics do not match the language semantics exactly. Long bytecode sequences are potentially required to achieve the desired language behavior. For example, Java bytecodes are statically typed, so compiling dynamically typed JavaScript requires frequent type checks. A simple addition in JavaScript requires checking whether the operands are numbers, strings, or arbitrary objects, which all require different handling. Therefore, implementations of JavaScript that run on a Java VM often call a method for a seemingly simple addition.

Dynamic type system:

Clojure features a dynamic type system. The Truffle framework was designed for high performance implementations for languages with a dynamic type system. As a consequence, the Clojure programming language could also benefit from the optimizations performed by Truffle-based interpreters.

How can we prove that this program works?

CLASSES OF RECURSIVELY ENUMERABLE SETS AND THEIR DECISION PROBLEMS(1)

BY

H. G. RICE

1. **Introduction.** In this paper we consider classes whose elements are recursively enumerable sets of non-negative integers. No discussion of recursively enumerable sets can avoid the use of such classes, so that it seems desirable to know some of their properties. We give our attention here to the properties of complete recursive enumerability and complete recursiveness (which may be intuitively interpreted as decidability). Perhaps our most interesting result (and the one which gives this paper its name) is the fact

RICE'S THEOREM (1957)

EVERY NON-TRIVIAL PROPERTY OF RECURSIVELY ENUMERABLE LANGUAGES IS UNDECIDABLE.

I. FUNDAMENTAL DEFINITIONS

Static typing - A set of rules to follow

```fortran
program fizzbuzz_if
   integer :: i

   do i = 1, 100
      if      (mod(i,15) == 0) then; print *, 'FizzBuzz'
      else if (mod(i,3) == 0) then; print *, 'Fizz'
      else if (mod(i,5) == 0) then; print *, 'Buzz'
      else;                         print *, i
      end if
   end do
end program fizzbuzz_if
```

Fortran (1957)

```fortran
program fizzbuzz_if
   integer :: i

   do i = 1, 100
      if      (mod(i,15) == 0) then; print *, 'FizzBuzz'
      else if (mod(i,3) == 0) then; print *, 'Fizz'
      else if (mod(i,5) == 0) then; print *, 'Buzz'
      else;                         print *, i
      end if
   end do
end program fizzbuzz_if
```

Fortran (1957)

Lower Bound of Correctness

```java
List<Integer> integers = new ArrayList<>();
List rawList = integers;

rawList.add("hello");

try {
    Integer num = integers.get(0);
} catch (ClassCastException e) {
    System.out.println("Error: " + e.getMessage());
}
```

Tradeoff: Easy to use / correct

Dynamic typing - Managing types at runtime

```
function add (a, b) {
return a + b;  }
```

RUNTIME

Value in Code

Value in Code

Everything is in Check

Runtime Exception

Runtime Exception

I'VE FINALLY FOUND the buggy line
Robotatertotcomics
console.log(_dasObject)
[Object object]
NYEHHH

Performance Overhead

```javascript
function add(x, y) {
    return x + y;
}

// Monomorphic usage
console.log(add(1, 2));
console.log(add(3, 4));

// Polymorphic usage
console.log(add(1, 2));
console.log(add("3", "4"));
```

Monomorphism, in the context of dynamic typing engine optimization, refers to a situation where a function is consistently called with arguments of the same type.

Dynamic Typing

Polymorphism: A function is called with arguments of different types. This requires the engine to handle multiple cases and can lead to less efficient code.

Megamorphism: A function is called with many different types of arguments, making it nearly impossible for the engine to optimize.

Dynamic Typing

Finally... back to Truffle

GraalVM in Truffle Mode

Language Interpreter

GraalVM in Truffle Mode

```java
import com.oracle.truffle.api.dsl.Specialization;
import com.oracle.truffle.api.dsl.TypeSystemReference;
import com.oracle.truffle.api.nodes.Node;
import com.oracle.truffle.api.nodes.NodeInfo;

@TypeSystemReference(MyTypeSystem.class) // Define the types recognized in your language
@NodeInfo(shortName = "add")
public abstract class AddNode extends Node {

    abstract Object execute(Object a, Object b);

    @Specialization
    protected int addIntegers(int a, int b) {
        return a + b;
    }

    @Specialization
    protected double addDoubles(double a, double b) {
        return a + b;
    }

    // Can add more specializations (e.g., for adding strings, booleans, etc.)
}
```

Abstract syntax tree

21 languages

Article Talk Read Edit View history Tools

From Wikipedia, the free encyclopedia

For the trees used in linguistics, see parse tree.

This article includes a list of references, related reading, or external links, **but its sources remain unclear because it lacks inline citations**. Please help improve this article by introducing more precise citations. *(February 2013) (Learn how and when to remove this template message)*

An **abstract syntax tree** (**AST**) is a data structure used in computer science to represent the structure of a program or code snippet. It is a tree representation of the abstract syntactic structure of text (often source code) written in a formal language. Each node of the tree denotes a construct occurring in the text. It is sometimes called just a **syntax tree**.

The syntax is "abstract" in the sense that it does not represent every detail appearing in the real syntax, but rather just the structural or content-related details. For instance, grouping parentheses are implicit in the tree structure, so these do not have to be represented as separate nodes. Likewise, a syntactic construct like an if-condition-then statement may be denoted by means of a single node with three branches.

This distinguishes abstract syntax trees from concrete syntax trees, traditionally designated parse trees. Parse trees are typically built by a parser during the source code translation and compiling process. Once built, additional information is added to the AST by means of subsequent processing, e.g., contextual analysis.

Abstract syntax trees are also used in program analysis and program transformation systems.

An abstract syntax tree for the following code for the Euclidean algorithm:

```
while b ≠ 0:
    if a > b:
        a := a − b
    else:
        b := b − a
return a
```

Application in compilers [edit]

Abstract syntax trees are data structures widely used in compilers to represent the structure of program code. An AST is usually the result of the syntax analysis phase of a compiler. It often serves as an intermediate representation of the program through several stages that the compiler requires, and has a strong impact on the final output of the compiler.

Motivation [edit]

An AST has several properties that aid the further steps of the compilation process:

```
function add(a, b) {
    return a + b;
}
```

A
What is type of a?

Abstract

An abstract syntax tree (AST) interpreter is a simple and natural way to implement a programming language. However, it is also considered the slowest approach because of the high overhead of virtual method dispatch. Language implementers therefore define bytecodes to speed up interpretation, at the cost of introducing inflexible and hard to maintain bytecode formats. We present a novel approach to implementing AST interpreters in which the AST is modified during interpretation to incorporate type feedback. This tree rewriting is a general and powerful mechanism to optimize many constructs common in dynamic programming languages. Our system is implemented in Java™ and uses the static typing and primitive data types of Java elegantly to avoid the cost of boxed representations of primitive values in dynamic programming languages.

Categories and Subject Descriptors D.3.4 [*Programming Languages*]: Processors—Run-time environments, Optimization

General Terms Algorithms, Languages, Performance

Keywords Java, JavaScript, dynamic languages, virtual machine, language implementation, optimization

studied [9, 22]. Bytecodes are a virtual instruction set, i.e, they can be defined freely by language implementers without worrying about hardware constraints. There are two different strategies when defining bytecodes. We believe that both are cumbersome when implementing a new language:

- Language-independent bytecodes aim to provide an instruction set that is suitable for many languages. Java™ bytecodes [17], originally designed primarily for the Java programming language, are now used for many languages. The Common Intermediate Language (CIL) [8], which is used by the .NET system, was specifically designed for multiple languages. Language-independent bytecodes provide only general instructions whose semantics do not match the language semantics exactly. Long bytecode sequences are potentially required to achieve the desired language behavior. For example, Java bytecodes are statically typed, so compiling dynamically typed JavaScript requires frequent type checks. A simple addition in JavaScript requires checking whether the operands are numbers, strings, or arbitrary objects, which all require different handling. Therefore, implementations of JavaScript that run on a Java VM often call a method for a seemingly simple addition.

PyPy (/ˈpaɪpaɪ/) is an implementation of the Python programming language.[2] PyPy often runs faster than the standard implementation CPython because PyPy uses a just-in-time compiler.[3] Most Python code runs well on PyPy except for code that depends on CPython extensions, which either does not work or incurs some overhead when run in PyPy.

PyPy itself is built using a technique known as meta-tracing, which is a mostly automatic transformation that takes an interpreter as input and produces a tracing just-in-time compiler as output. Since interpreters are usually easier to write than compilers, but run slower, this technique can make it easier to produce efficient implementations of programming languages. PyPy's meta-tracing toolchain is called RPython.

Partial evaluation is a key optimization technique where the Truffle framework precomputes parts of the program based on known inputs and constant values at compile time.

This results in highly optimized machine code for guest languages, significantly improving the performance of language interpreters built with Truffle.

Partial Evaluation

Compilers for free with weval

May 19, 2024

Chris Fallin came and gave a talk to the Northeastern Programming Research Laboratory last month. He talked about his work on a new project called weval, a WebAssembly partial evaluator (and then helped me write this post!).

Partial evaluation is neat. In short, it's all about taking an existing program, modifying it to hold some of its inputs as constants, and then letting the compiler/optimizer go hog wild on it. The result is still a program—not a value—and it's usually faster than the original program.

The usual small example is the power function. If you have a function that takes two arguments, `x` and `y`, and returns `x^y`:

```
int power(int x, int y) {
  int result = 1;
  for (int i = 0; i < y; i++) {
    result *= x;
  }
  return result;
}
```

If you partially evaluate this function with respect to `y` at `y = 5`, you get a new function that takes one argument, `x`, and returns `x^5`:

```
int power_5(int x) {
  int result = 1;
  for (int i = 0; i < 5; i++) {
    result *= x;
  }
  return result;
}
```

Now, to you, this might not look that different from the original function. But to an optimizer, it is a new world of opportunity. The optimizer can unroll the loop and remove the conditional:

```
int power_5(int x) {
  return x * x * x * x * x;
}
```

For the past couple of years, Truffle languages were installed using our built-in GraalVM Updater tool called `gu`. To install a language, you downloaded Oracle GraalVM and then ran the `gu install` command to download and unpack components. Together with the GraalVM for JDK 21 and Truffle/Polyglot 23.1 releases, we remove `gu` and provide languages as Maven dependencies instead. In this blog post, we want to dive into why this change was necessary, what we gain from it, and what you need to do to

GraalVM as library

```
dependencies {
    implementation("org.graalvm.polyglot:polyglot:23.1.0")
    // Select language: js, ruby, python, java, llvm, wasm, languages
    implementation("org.graalvm.polyglot:js:23.1.0")
}
```

Maxine Virtual Machine

1 language

Article Talk Read Edit View history Tools

From Wikipedia, the free encyclopedia

This article has multiple issues. Please help **improve it** or discuss these issues on the **talk page**. *(Learn how and when to remove these template messages)* [hide]

- This article includes a list of general references, but **it lacks sufficient corresponding inline citations**. *(August 2012)*
- This article **relies excessively on references to primary sources**. *(June 2011)*

The **Maxine** virtual machine is an open source virtual machine that is developed at the University of Manchester.[2] It was formerly developed by Sun Microsystems Laboratories,[3] since renamed Oracle Labs. The emphasis in Maxine's software architecture is on modular design and code reuse for flexibility, configurability, and productivity for industrial and academic virtual machine researchers. It is one of a growing number of Java virtual machines written entirely in Java in a meta-circular style. Examples include Squawk and Jikes RVM.

Maxine

Original author(s)	Bernd Mathiske, Douglas Simon (Sun Labs, Oracle)
Developer(s)	University of Manchester, Maxine team
Initial release	2005; 19 years ago
Stable release	2.9.0[1] / December 20, 2019; 4 years ago
Repository	github.com/beehive-lab/Maxine-VM
Written in	Java
Operating system	Solaris, Linux, macOS
Platform	x64, ARM32, AArch64, RISC-V
Type	Java virtual machine
License	GPL version 2.0
Website	github.com/beehive-lab/Maxine-VM

Architecture [edit]

The Maxine VM is characterized internally by aggressive use of advanced language features in Java 1.5 and 1.6, by modular subsystems coordinated through Java interfaces, by the absence of an interpreter, and by a tightly coupled debugger and visualization tool for VM development.

Compatibility [edit]

Maxine is plug compatible with an unmodified Java Development Kit (JDK). Maxine can be developed, built, and run in standard Java integrated development environments (IDEs), including NetBeans, Eclipse, and IntelliJ IDEA.

Espresso

What performance can I expect from executing Java on Truffle?

Performance is currently 2-3x slower than HotSpot. It does not match the speed offered by GraalVM yet for sure, but having created a fully working Java on Truffle runtime, the development team is now focusing on making it as performant as the GraalVM JIT.

Does Java running on Truffle run on HotSpot too?

Like other languages implemented with the Truffle framework, it can run both as a native executable or on top of HotSpot. Running on top of HotSpot is currently only possible on Linux. We plan to extend this capability to macOS and Windows platforms also.

```
Exception in thread "main" Espresso cannot evaluate Java sources directly, only a few special commands are
supported: <Bindings> and <ProcessReferences>
Use the "java" language bindings to load guest Java classes e.g.
context.getBindings("java").getMember("java.lang.Integer")
```

Native JShell and Espresso: Mixing AOT and JIT for Java

This demo showcases the integration between GraalVM Native Image and Java-on-Truffle (Espresso).
It builds a native executable version of `jshell`, that executes the dynamically generated bytecodes on Espresso. This hybrid mode achieves instant startup, beating the vanilla `jshell` in both: time to the first interaction and time to evaluate a simple expression.

JShell is a Java read-eval-print loop tool first introduced in Java 9, this demo also allows running `jshell` on Java 8.
For further discussions and questions please join our `#espresso` channel on the GraalVM Slack Community.

Prerequisites

- GraalVM for Java 11, 17 or higher
- Native Image support
- Java-on-Truffle (Espresso) support

Preparation

1. Download and install the latest GraalVM JDK with Native Image and Java on Truffle (Espresso) components using the GraalVM JDK Downloader.

   ```
   bash <(curl -sL https://get.graalvm.org/jdk) -c 'espresso'
   ```

   The download script will provide the `JAVA_HOME`, `PATH`, and `GRAALVM_HOME` environment variables (follow the command line prompt).

2. Download or clone GraalVM demos repository and navigate into the `espresso-jshell` directory:
